

# **Validation of IAU initialized reforecasts with updated snow depth and IAU replay (2000-2018)**

Hong Guan, Kate Zhou, Yuejian Zhu, Bing Fu  
Environmental Modeling Center  
NCEP/NWS/NOAA

Acknowledgments:  
Scott Gregory, Jeff Whitaker and PSD staffs,  
and Ensemble staffs,  
Update: 5/23/2019

# Motivation and Background

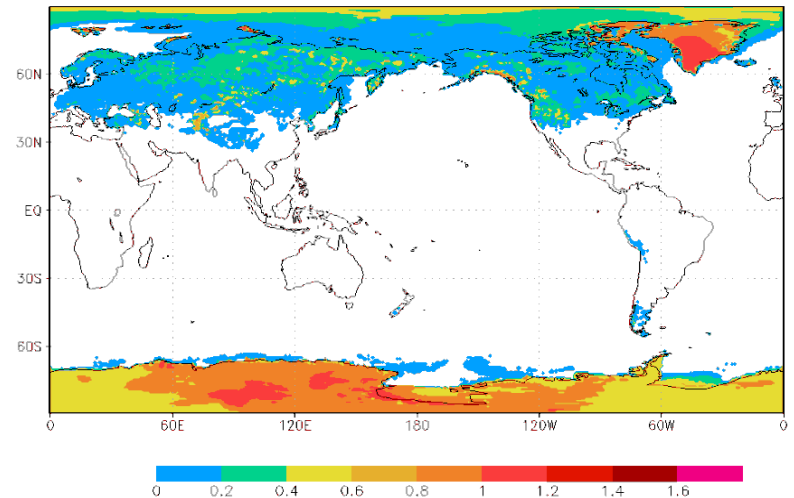

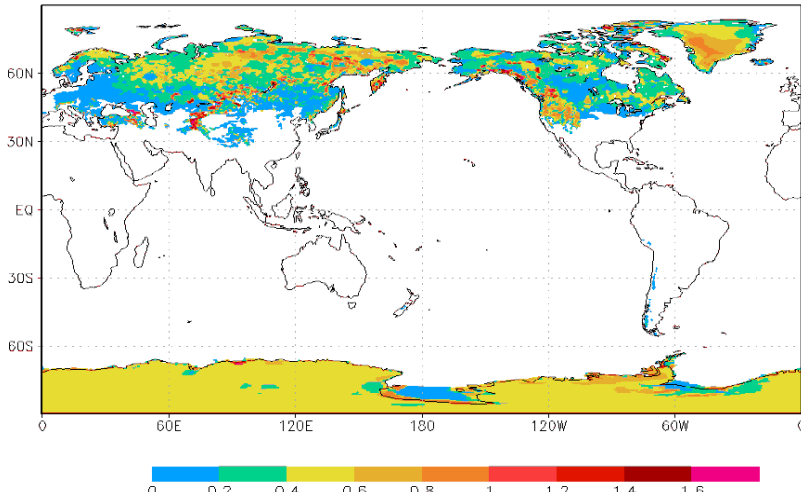

- The simulation with the old snow depth (see Guan's presentation in Feb. 28) shows that:
  - The T2M for the reforecast run for Jan. 1-7 2016 is much warmer than the retrospective run in the NH land, particular in the **center of Asia-Europe and North America** from analysis to forecast.
  - The large difference is moving slowly to northeast.
- This large warm bias is mainly attributed to much less snow in reanalysis.  
(The snow depth climatology is used for 00Z, 06Z and 12Z with the envelop method.)

# Old snow depth (1)

2017010418 snow depth - BUFR dump OBS

2017010418 snow depth - REanalysis

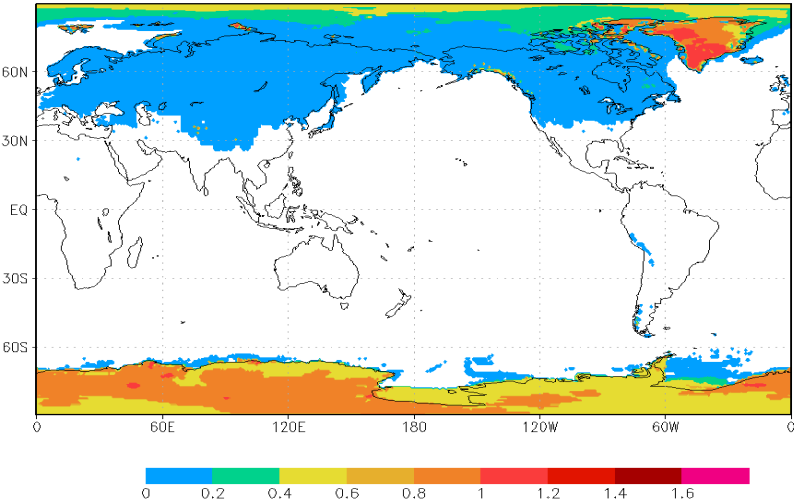

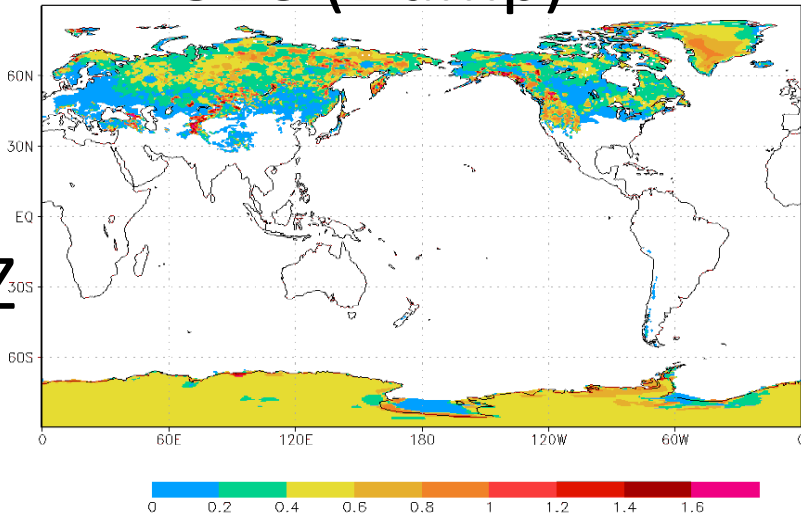

18Z

2017010500 snow depth - BUFR dump OBS

2017010500 snow depth - REanalysis

00Z

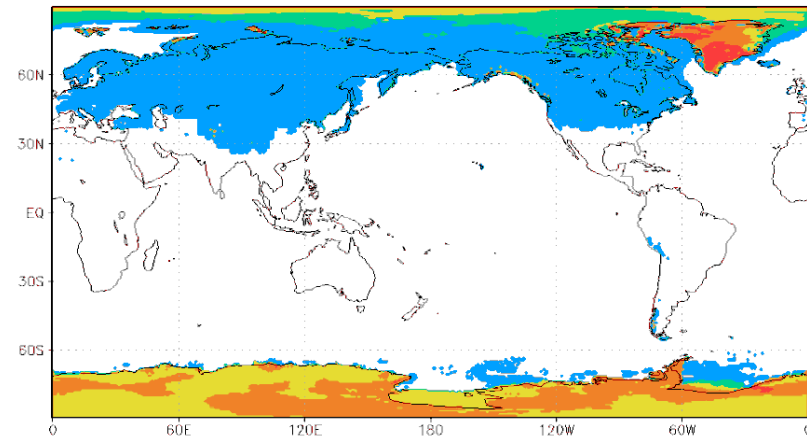

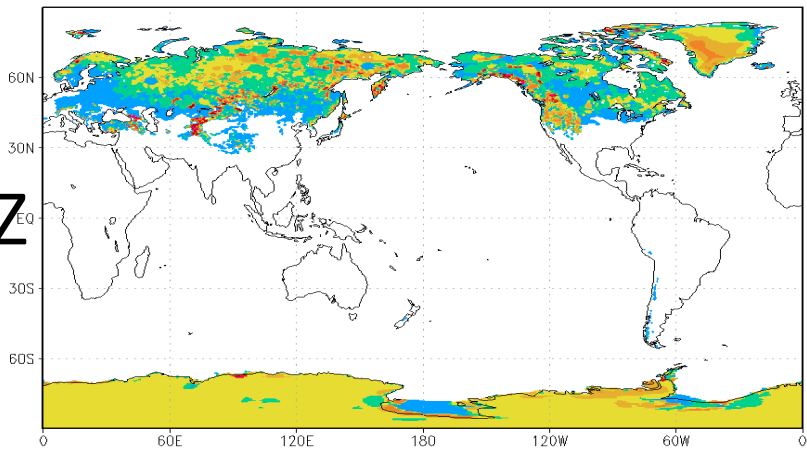

Over NH, Snow depth in Re-analysis for 18Z (00Z) is smaller (much smaller) than OBS.

# Old snow depth (2)

2017010506 snow depth - BUFR dump OBS

2017010506 snow depth - REanalysis

06Z

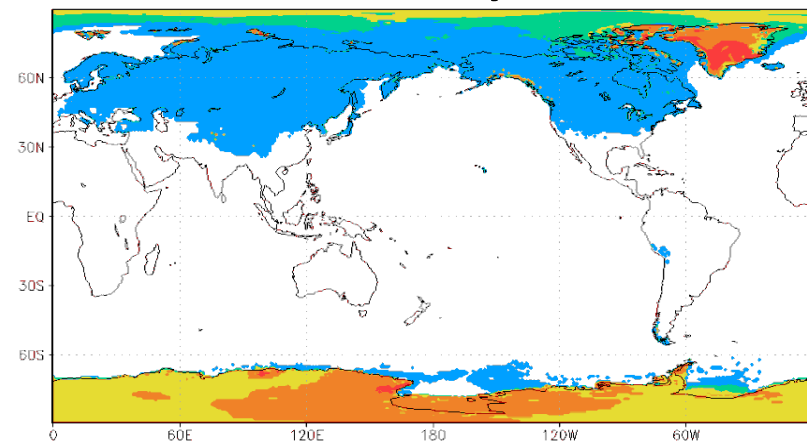

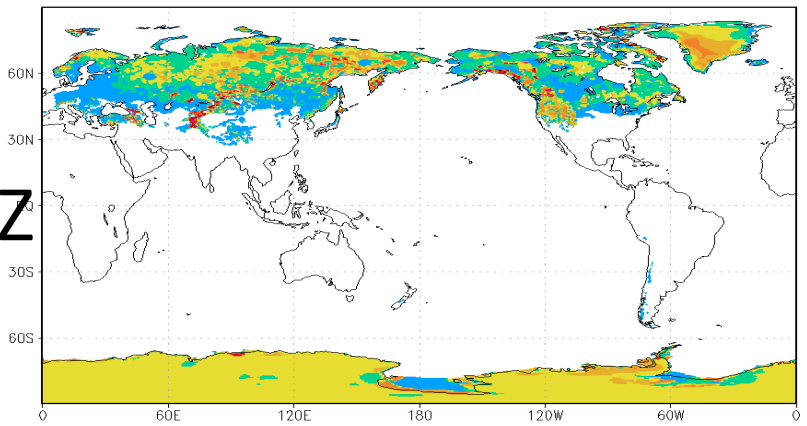

OBS (Dump)

Re-analysis

2017010512 snow depth - BUFR dump OBS

2017010512 snow depth - REanalysis

12Z

Over NH, snow depth in Re-analysis for 06Z and 12Z is much smaller than OBS.

# Updated snow depth and snow equivalent water

SNWDPH

WEASD

snwdph (none)

sheleg (none)

OLD

snwdph (none)

sheleg (none)

NEW

Over NA and Europe, both SNWDPH and WEASD in new Re-analysis are much increased.

# Evaluation

# Experiment Setting

- Period:
  - 28 cases for winter – 1/1 – 1/29/2016
    - 5 members per run out to 16 days
    - **Missing one IAU restarted initial condition**
- Model configuration
  - Frozen system (Dec. 21 2018)
    - Highlights – Hord=5; radiation bug fixed; SST adjustment; GFDL MP modification
  - Initial conditions
    - End of IAU (+3), and perturbations (EnKF analysis) with re-centerization.
    - Retrospective initials are using **hybrid DA cycling (June 2018 version)** and F06 of ENKF
- References:
  - Forecasts (using IAU replay with right snow depth)
  - compare to retrospective experiments – only difference is a initial conditions
  - Verification reference – **Own analysis (Reanl – YYYYMMDD06...fhr00)**

# Summary

- For IAU replay – statistical scores
  - The differences for Z500, T850, U10m between retrospective runs and reforecast runs are small.
  - The difference for T2m – reforecast shows less RMS error, but more cold bias
- For IAU replay – spatial differences
  - The difference of T2m analyses (or F00) are still large for NH high latitude land, which may still impact from snow depth.
  - The difference between reforecast and retrospective forecast is still visible for longer lead time, but much smaller.
- Recommendation
  - Could we re-start to run reforecast if there is no against and no other option?
  - We'd like to hear CPC's comments
- **Major concerns:**
  - **Analysis (or f00) for T2m:**
    - **The difference is still larger comparing to retrospective – see slide #12**
    - **If there is no consistent T2m as reference (f00), it is challenge to estimate model bias even we have consistent model forecast.**
    - **Should we use ERA40 as best reference, particular for T2m?**
